

Common Vulnerabilities in OO Systems

Here's a list of common vulnerabilities in OO systems:

Injection Attacks: This occurs when untrusted data is sent to an interpreter as part of a command or query (e.g., SQL injection). Example: A malicious user inputs SQL code into a login form, bypassing authentication.

Buffer Overflows: This occurs when a program writes more data to a buffer than it can hold, potentially overwriting adjacent memory. Example: Exploiting a buffer overflow to execute arbitrary code.

Insecure Object References: This occurs when an attacker gains access to objects they should not have access to (e.g., accessing another user's data).

Improper Error Handling: This is revealing sensitive information (e.g., stack traces) in error messages.

Broken Authentication: This happens when weak authentication mechanisms that allow attackers to compromise user accounts.
